**ABSTRACT**

Multimodal biometric system is an important part of biometric system which is consist of multiple biometric traits for human identification. These biometric traits are varying as per ageing and some are unchanged. Therefore, combination of human biometric traits is used for better performance. These changes are identifying using adaptive feature set algorithm which will trigger when there updating is required.

For security purpose we implementing Blockchain technology using Hyperledger fabric on Multimodal biometric system to track the entire system and reduced frauds. Once the transactions are recorded in the ledger then it is hard to modify or delete the record. Blockchain technology is unalterable.

**Keywords**—Blockchain technology, Hyperledger fabric, Smart Contract, Multimodal Biometric, AFSU algorithm, Docker.

**I. INTRODUCTION**

Multimodal Biometrics is a combination of multiple biometric feature for human identification. A biometric-based authentication process is done by using two modes: Enrollment and Authentication. In enrollment mode, a user's biometric data is read by biometric and stored in a database. In authentication mode, data which is acquired using enrollment mode is use to verify the claimed identity of the user or identify who the user is. While this verification is done using data corresponding to all users in the database. There are two types of user's biometric feature: Un-changed and Varying. In this system, the data which is use for user's biometric identification is stored in the database by implementing blockchain technology on it [1].

In Multimodal biometric system, system authentication is done by using combination of human features. There are two types of human features: Changed and Unchanged human biometric features. The changed features like face, voice, signature have low degree of permanence and they vary with time whereas unchanged features like Iris, retina, fingerprint have high degree of permanence and do not vary with time. Adaptive Feature Set Algorithm is used to monitor the changes occurring in the human biometric features due to some reason, identify need of replace the feature and triggered update module.

Biometric system is use for human identification. This verification is done using data corresponding to all users in the database. Biometric system is secured itself but it is totally dependent on the database therefore there is need of database security and by identifying this drawback we implementing blockchain technology on it. The data is stored through blockchain technology is secured and unalterable, therefore anyone cannot modify or delete the data from database.

Blockchain technology is referred as Distributed Ledger Technology (DLT), makes the record or history of transactions happened between two parties or any digital asset unalterable and transparent through the use of decentralization and cryptographic hashing [2].

A smart contract used in blockchain technology is nothing but a set of rules written in programming language. A smart contract is referred as an agreement between the two parties to perform any transaction over internet. A smart contract executes independently by the blockchain, there is no third-party involvement is present [3].

Hyperledger fabric is a blockchain framework on which you can build your own blockchain applications. Hyperledger fabric is open source project which is founded by Linux Foundation in 2015. In Hyperledger fabric, all participants must enroll through a trusted Membership Service Provider (MSP), before they can be part of the network, so it provides proof of trusted party. No transaction is allowed without verifying the participant. It is not a public network like Ethereum or bitcoin, it is a permissioned network or private network. In this, participants can be allowed to invoke smart contract, but not allowed to deploy any new smart contract. The smart contract written in Hyperledger fabric is called as Chaincode. No specific currency is required there is freedom for token/ coin [3].

## **II. EXISTING SYSTEM**

In existing system, multimodal biometrics which is an emerging domain in biometric technology for enhance the performance of combination of more than one biometric trait that is used to adapt future changes in biometrics like face, iris, thumb, signature, voice and gait with respect to time. These biometric-based systems use two modes that are enrollment and authentication. Author Ujwalla Gawand [4] proposed a system that adapts a unified viewpoint to extract singular points (core and delta) that determine the topological structure and largely influence the orientation field by using the principle of Gabor basis functions.

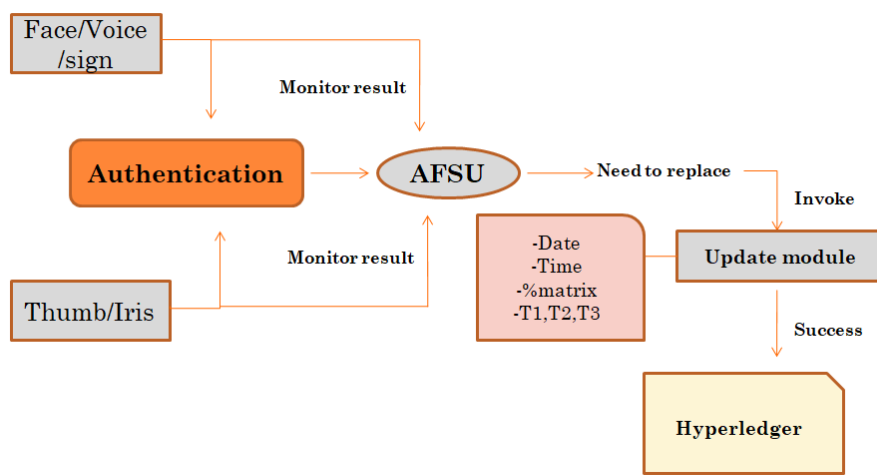

Author Shyam Sundar Yadav [5] proposed five important modules that: The Sensor module which is interface between real world and system, the Feature Extraction module which removes artifacts from sensor, the Matching module extracts features which we have to choose with certain efficiency to create a template and match the input pattern and the database pattern with the pattern matching technique, Decision module and System Database module, authentication occurs based on pattern matching techniques.

Author Dr. Vinayak Bharadi [1] proposed a system that uses Adaptive Feature Set Update Algorithm to track the changes in biometrics and update the feature set securely which can take different biometric inputs for face recognition, finger print scan for finger identification for future extraction and representation. Biometric uses features related to human body which are change with age or some physical changes. Some high degree performance features like fingerprint, iris do not vary with respect to time but features like voice, face have low degree of performance which can be vary with time due to some physical changes. The existing system takes these types of features for enrolling feature set for multimodal biometric that can adopt changes in biometric traits with AI which are used for human identification.

Author Senthil Nathan proposed a system that design and implement first-ever decentralized replicated relational database with Blockchain properties that we term blockchain relational database. Author Shu Yun Lim [6] proposed a blockchain system that perform identity management and authentication which is distributed, fault tolerance and decentralized. The system facilitates peer-to-peer exchange of sensitive data, maintain privacy to providing efficiency and cost-effective identity management framework.

### III. PROPOSED SYSTEM

Here, we are explaining our proposed system Fig. 3.1 which used multimodal biometric features like face, voice, signature, thumb, iris, etc. which are changed or unchanged for human identification. Face, voice, signature is changing features and thumb, iris are unchanging features. When these features are used for system authentication as an input with the help of biometric devices. That authentication results comes from changing and unchanging feature traits which are monitored with the help of Adaptive feature Set Update Algorithm which is used for feature extraction. If there is a need to replace the features which are change due to some physical changes or ageing then update is triggered with the help of update module. Update module invokes those changes. When system authentication is done successfully then biometric system record that entries with date, time, %matrix and timestamps, so anybody cannot be denying the entries [1]. When user performs any transaction then smart contract is execute or trigger by blockchain which is written in Hyperledger fabric.

**Fig. 3.1 Architecture of proposed system**

- ❖ The Hyperledger contains 3 main components:
  - A. **Endorser Peer** – Receives data entries request from client application and validates the data and roles of requester. This executes the chain code (i.e. smart contract) and simulates the transaction but, it does not update the ledger. It approves and disapproves the transaction.
  - B. **Anchor Peer** – It configures the secret channels among the peer and data among the peer of that channel is visible only to them. It receives the updates and broadcast the updates to the other peers.
  - C. **Ordering Peer** – It is the central communication channel for Hyperledger network. It is responsible for consistent ledger state across the network. It creates the blocks and delivers that to all the peers.

❖ The Hyperledger workflow Fig. 3.2 is given as follows:

**Step 1:** User request for data entry to client application.

**Step 2:** Client Application broadcast data entry invocation entry to Endorser peer.

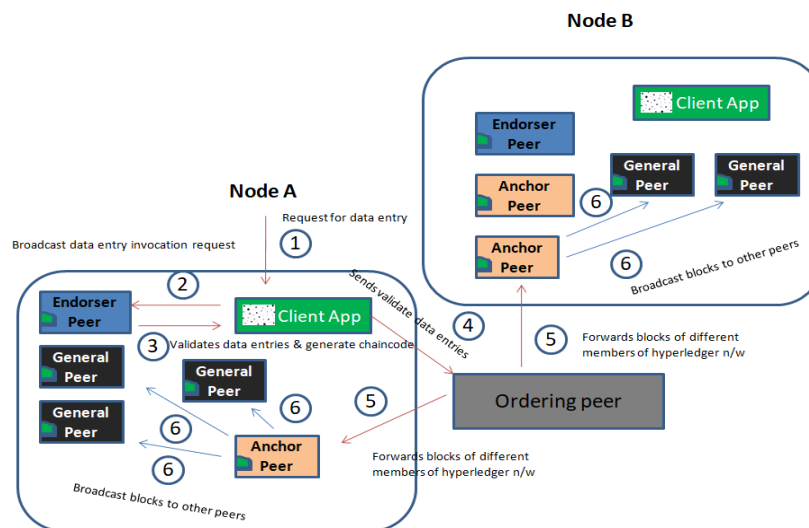

**Step 3:** Endorser peer validate that data entries and generate Chaincode i.e. smartcontract to client application.

**Step 4:** Client application send validate data entries to the Ordering peer which generates blocks of data.

**Step 5:** Ordering peer forwards these blocks of different members to Anchor peer of Hyperledger network.

**Step 6:** Anchor peer broadcast blocks to other General peers.

**Step 7:** These individual peers then updates their local ledger with latest block.

**Fig. 3.2 Data Flow Diagram**

## IV. RESULT

### ❖ To install Hyperledger Fabric on Linux:

1. Execute the following commands to update the software on your system:

```
sudo apt-get update
```

2. Install curl and the golang software package:

```
sudo apt-get install curl
```

```
sudo apt-get install golang
```

```
export GOPATH=$HOME/go
```

```
export PATH=$PATH:$GOPATH/bin
```

3. Install Node.js, npm, and Python

```
sudo apt-get install nodejs
```

```
sudo apt-get install npm
```

```
sudo apt-get install python
```

4. Install and upgrade docker and docker-compose:

```
$ sudo apt-get install docker
```

```
curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -  
  
sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu  
  
$(lsb_release -cs) stable"  
  
$ sudo apt-get update  
  
$ apt-cache policy docker-ce  
  
sudo apt-get install -y docker-ce  
  
sudo apt-get install docker-compose  
  
sudo apt-get upgrade
```

```
curl 7.47.0 (x86_64-pc-linux-gnu) libcurl/7.47.0 GnuTLS/3.4.10 zlib/1.2.8 libidn/1.32 librtmp/2.3  
Protocols: dict file ftp ftps gopher http https imap imaps ldap ldaps pop3 pop3s rtmp rtsp smb smbs smtp smtps telnet tftp  
Features: AsynchDNS IDN IPv6 Largefile GSS-API Kerberos SPNEGO NTLM NTLM_WB SSL libz TLS-SRP UnixSockets  
go version go1.11.2 linux/amd64  
Python 2.7.12  
v8.15.0  
6.4.1  
Docker version 18.09.0, build 4d60db4  
docker-compose version 1.8.0, build unknown
```

5. Install Hyperledger Fabric 1.3:

```
$ curl -sSL http://bit.ly/2ysbOFE | sudo bash -s 1.3.0
```

Download Docker images:

```

#### ❖ Build Hyperledger Fabric Network:

1. Log in as a default user and execute the byfn.sh script to generate certificates and keys for the network:

```
$ cd ~  
sudo chmod 777 -R fabric-samples  
cd fabric-samples/first-network  
sudo ./byfn.sh generate
```

2. Bring up the Fabric network by executing the byfn.sh script using the up option:

```
$ cd ~  
cd fabric-samples/first-network  
sudo ./byfn.sh up
```

The network has started successfully:

```

ubuntu@ip-172-31-78-117:~/fabric-samples/first-network$ sudo ./byfn.sh up
Starting for channel 'mychannel' with CLI timeout of '10' seconds and CLI delay of '3' seconds
Continue? [Y/n] Y
proceeding ...
LOCAL_VERSION=1.3.0
DOCKER_IMAGE_VERSION=1.3.0
Creating network "net_byfn" with the default driver
Creating volume "net_peer0.org2.example.com" with default driver
Creating volume "net_peer1.org1.example.com" with default driver
Creating volume "net_peer0.org1.example.com" with default driver
Creating volume "net_orderer.example.com" with default driver

Creating peer1.org2.example.com
Creating orderer.example.com
Creating cli

  S T A R T

Build your first network (BYFN) end-to-end test
    
```

3. Bring down the Fabric network by executing the byfn.sh script using the down option to shut down and clean up the network. This kills the containers, removes the crypto material and artifacts, and deletes the chaincode images. The following code shows how to do this:

```

$ cd ~
cd fabric-samples/first-network
sudo ./byfn.sh down
    
```

The byfn.sh script, shown as follows. This script is well documented, and you should read about it in detail to understand each execution step during the network startup process:

```

# Print the usage message
function printHelp() {
  echo "Usage: "
  echo "  byfn.sh <mode> [-c <channel name>] [-t <timeout>] [-d <delay>] [-f <docker-compose file>] [-s <dbtype>] [-l <language>] [-i <imagetag>] [-v]"
  echo "  <mode> - one of 'up', 'down', 'restart', 'generate' or 'upgrade'"
  echo "  - 'up' - bring up the network with docker-compose up"
  echo "  - 'down' - clear the network with docker-compose down"
  echo "  - 'restart' - restart the network"
  echo "  - 'generate' - generate required certificates and genesis block"
  echo "  - 'upgrade' - upgrade the network from version 1.2.x to 1.3.x"
  echo "  -c <channel name> - channel name to use (defaults to 'mychannel')"
  echo "  -t <timeout> - CLI timeout duration in seconds (defaults to 10)"
  echo "  -d <delay> - delay duration in seconds (defaults to 3)"
  echo "  -f <docker-compose file> - specify which docker-compose file use (defaults to docker-compose-cli.yaml)"
  echo "  -s <dbtype> - the database backend to use; goleveldb (default) or couchdb"
  echo "  -l <language> - the chaincode language; golang (default) or node"
  echo "  -i <imagetag> - the tag to be used to launch the network (defaults to 'latest')"
  echo "  -v - verbose mode"
  echo "  byfn.sh -h (print this message)"
  echo
  echo "Typically, one would first generate the required certificates and "
  echo "genesis block, then bring up the network, e.g.:"
  echo
  echo "  byfn.sh generate -c mychannel"
  echo "  byfn.sh up -c mychannel -s couchdb"
  echo "  byfn.sh up -c mychannel -s couchdb -i 1.2.x"
  echo "  byfn.sh up -l node"
  echo "  byfn.sh down -c mychannel"
  echo "  byfn.sh upgrade -c mychannel"
  echo
  echo "Taking all defaults:"
  echo "  byfn.sh generate"
  echo "  byfn.sh up"
  echo "  byfn.sh down"
}
    
```

The following command will generate the YAML file:

```

$ cd ~
$ cd fabric-samples/first-network
$ sudo ../bin/cryptogen generate --config=./crypto-config.yaml
    
```

We write the blockchain genesis block, create the first channel transaction, and write anchor peer updates. You may not care how exactly it is done, but this is how Fabric is built from the bottom up. You can see that four new files are generated and stored in the channel-artifacts directory:

- genesis.block
- channel.tx
- Org1MSPanchors.tx
- Org2MSPanchors.tx

```
$ export FABRIC_CFG_PATH=$PWD
sudo ../bin/configtxgen -profile TwoOrgsOrdererGenesis -outputBlock ./channel-artifacts/genesis.block
export CHANNEL_NAME=mychannel
sudo ../bin/configtxgen -profile TwoOrgsChannel
```

```
-outputCreateChannelTx ./channel-artifacts/channel.tx -channelID $CHANNEL_NAME
sudo ../bin/configtxgen -profile TwoOrgsChannel
```

```
-outputAnchorPeersUpdate ./channel-artifacts/Org1MSPanchors.tx -channelID $CHANNEL_NAME -
asOrg Org1MSP
sudo ../bin/configtxgen -profile TwoOrgsChannel
-outputAnchorPeersUpdate ./channel-artifacts/Org2MSPanchors.tx -channelID $CHANNEL_NAME -
asOrg Org2MSP
```

6. The Docker Compose tool is used to bring up Docker containers. We use docker-compose-cli.yaml to keep track of all Docker containers that we bring up:

```
$ cd ~
$ cd fabric-samples/first-network
$ sudo docker-compose -f docker-compose-cli.yaml up -d
```

7. We have brought up six nodes: cli, orderer.example.com, peer0.org1.example.com, peer0.org2.example.com, peer1.org1.example.com, and peer1.org2.example.com:

```
ubuntu@ip-172-31-78-117:~/fabric-samples/first-network$ sudo docker-compose -f docker-compose-cli.yaml up -d
Creating network "net_byfn" with the default driver
Creating volume "net_peer0.org2.example.com" with default driver
Creating volume "net_peer1.org2.example.com" with default driver
Creating volume "net_peer1.org1.example.com" with default driver
Creating volume "net_peer0.org1.example.com" with default driver
Creating volume "net_orderer.example.com" with default driver
Creating peer1.org1.example.com
Creating peer1.org2.example.com
Creating peer0.org2.example.com
Creating peer0.org1.example.com
Creating orderer.example.com
Creating cli
```

## CONCLUSION

The multimodal biometric systems overcome the problems in unimodal biometric systems. To facilitate peer-to-peer exchange of data and consent, mechanisms for discovery and recording of biometric traits, a decentralized network that is publicly accessible, immutable and resistant to faults and tampering is needed. Distributed ledger technology and Blockchain is the revolution that makes this possible. The approach used here is to increase accountability and efficiency as well as security of the entire system. Blockchain based solution is to produce integrity and protect system from single-point-of-failure. The Hyperledger of the blockchain, contains all the transactions information, is distributed and available to every member of the blockchain network. So, the blockchain-based identity management for user authentication using Adaptive Feature Set Update Algorithm is proposed for preserving privacy. This is the novel key management mechanism for blockchain-based security for user authentication. Performance and the advanced security level with blockchain technology made the multi-modal biometric systems popular in nowadays.
